

1

Install Rust

**[rust-lang.org/tools/install](https://rust-lang.org/tools/install)**

2

Create a Project

Run  
*cargo new <projectname>*  
at the terminal

3

Setup VSCode

Install the *rust-analyzer* extension

4

Write code!

Let's do it!

1

Install Rust

**[rust-lang.org/tools/install](https://rust-lang.org/tools/install)**

## ***Project #1***

Write a Rust program that simulates a deck of playing cards

*Cargo is used to create, compile, run, and manage projects*

Create a new project

```
cargo new <projectname>
```

Run a project

```
cargo run
```

We want to store some data and attach some functionality to it

In Rust, a good tool for this is a **struct**

Structs are kind of like classes from other languages

Name of the struct, always capitalized

```
struct Deck {  
  cards: Vec<String>  
}
```

List of fields (data) that this struct will wrap up

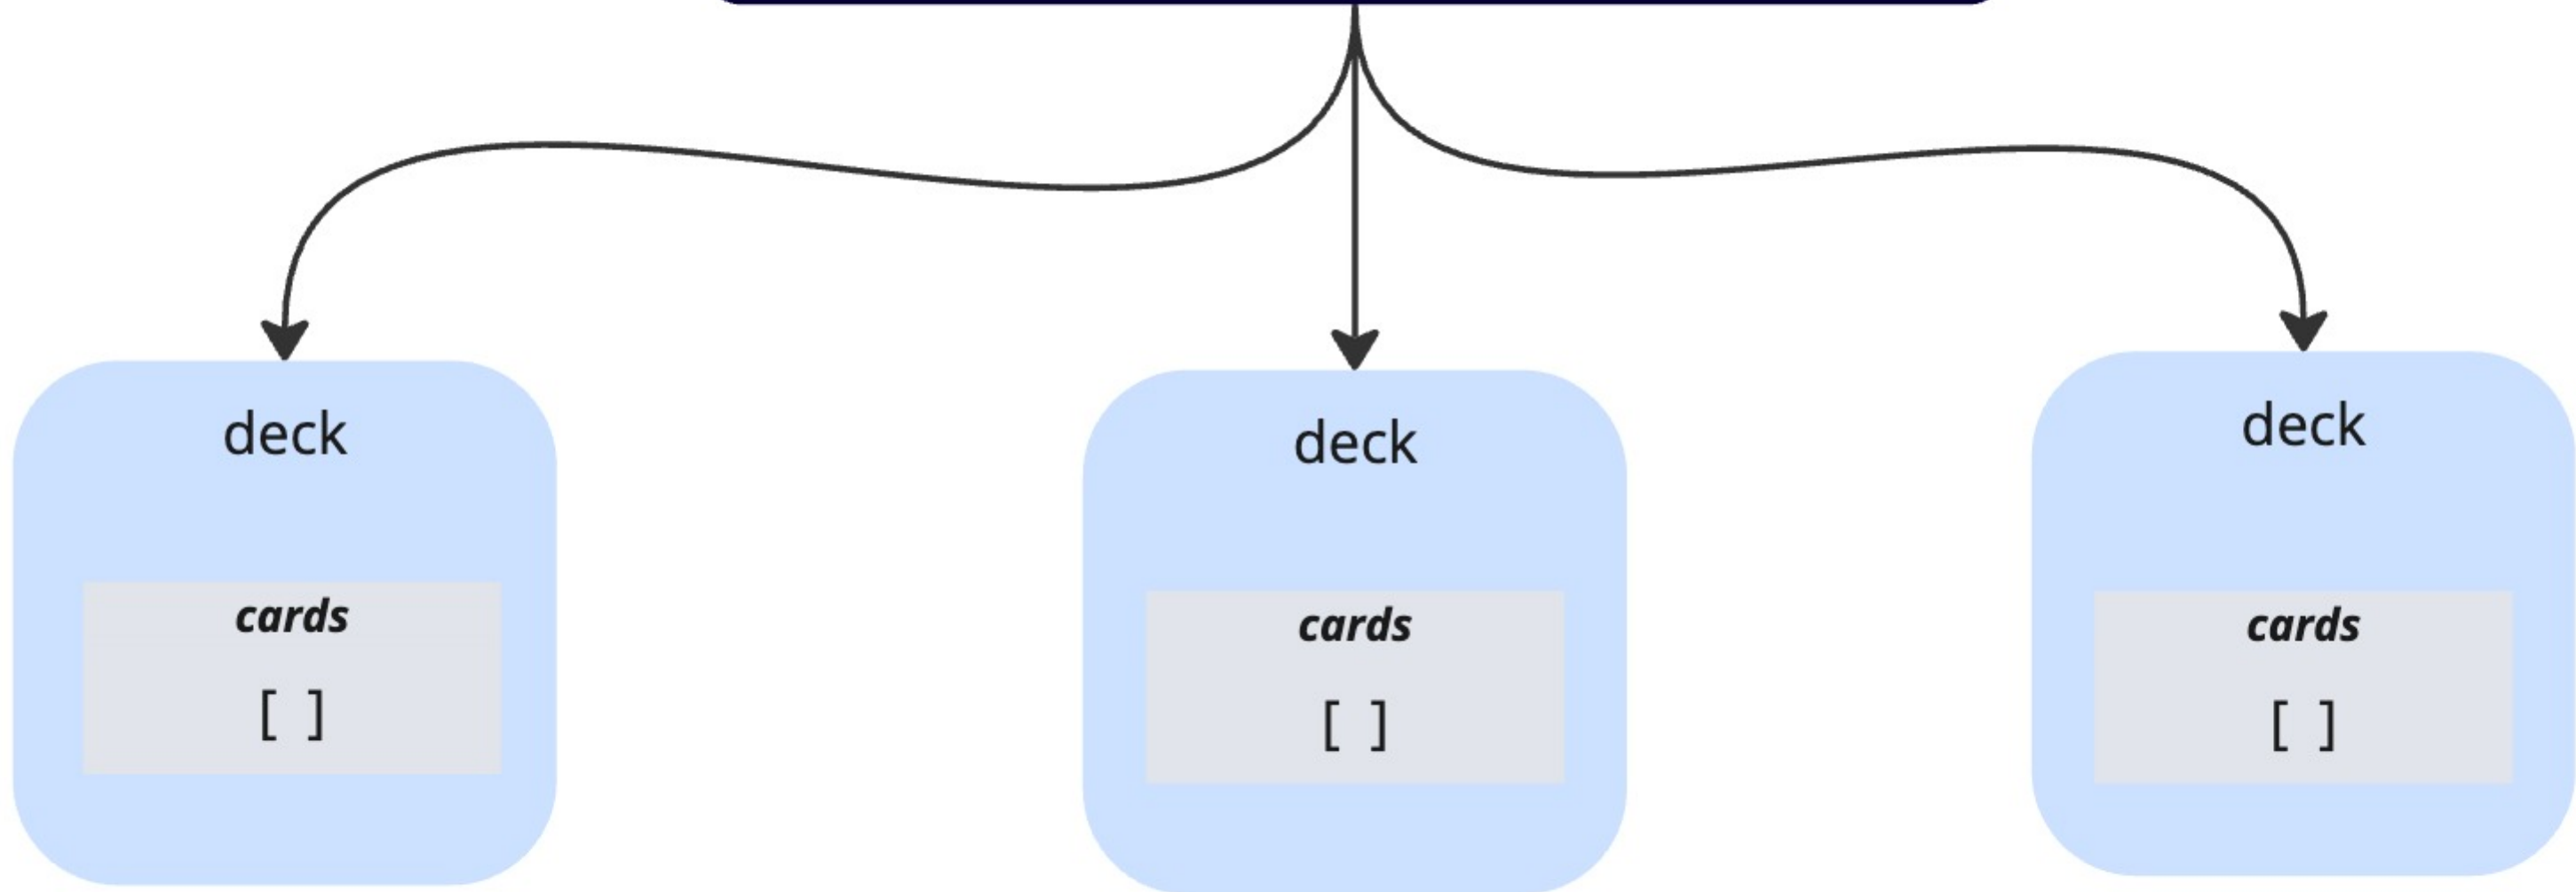

Vector that will contain strings.

Vectors are like arrays that can **grow/shrink** in size

Rust also has 'arrays'. They have **fixed lengths**

## Struct Definition

```
struct Deck {  
    cards: Vec<String>  
}
```

Instances of the 'Deck' struct

Declares a new  
*binding* (variable)

Struct literal.  
Creates an instance of a struct

```
let deck: Deck = Deck { cards: vec![] };
```

Type annotation.  
Describes the type of  
value 'deck' refers to

Creates an empty vector.  
Again, the "!" indicates a  
macro

*More on macros later*

```
#[derive(Debug)]
```

```
struct Deck {  
    cards: Vec<String>,  
}
```

Whole statement defines 'attributes' for the Deck struct

Gives the rust compiler some extra instructions

```
#[derive(Debug)]
```

```
struct Deck {  
    cards: Vec<String>,  
}
```

Called the 'derive attribute'

Specifies which 'traits' to automatically implement for this struct

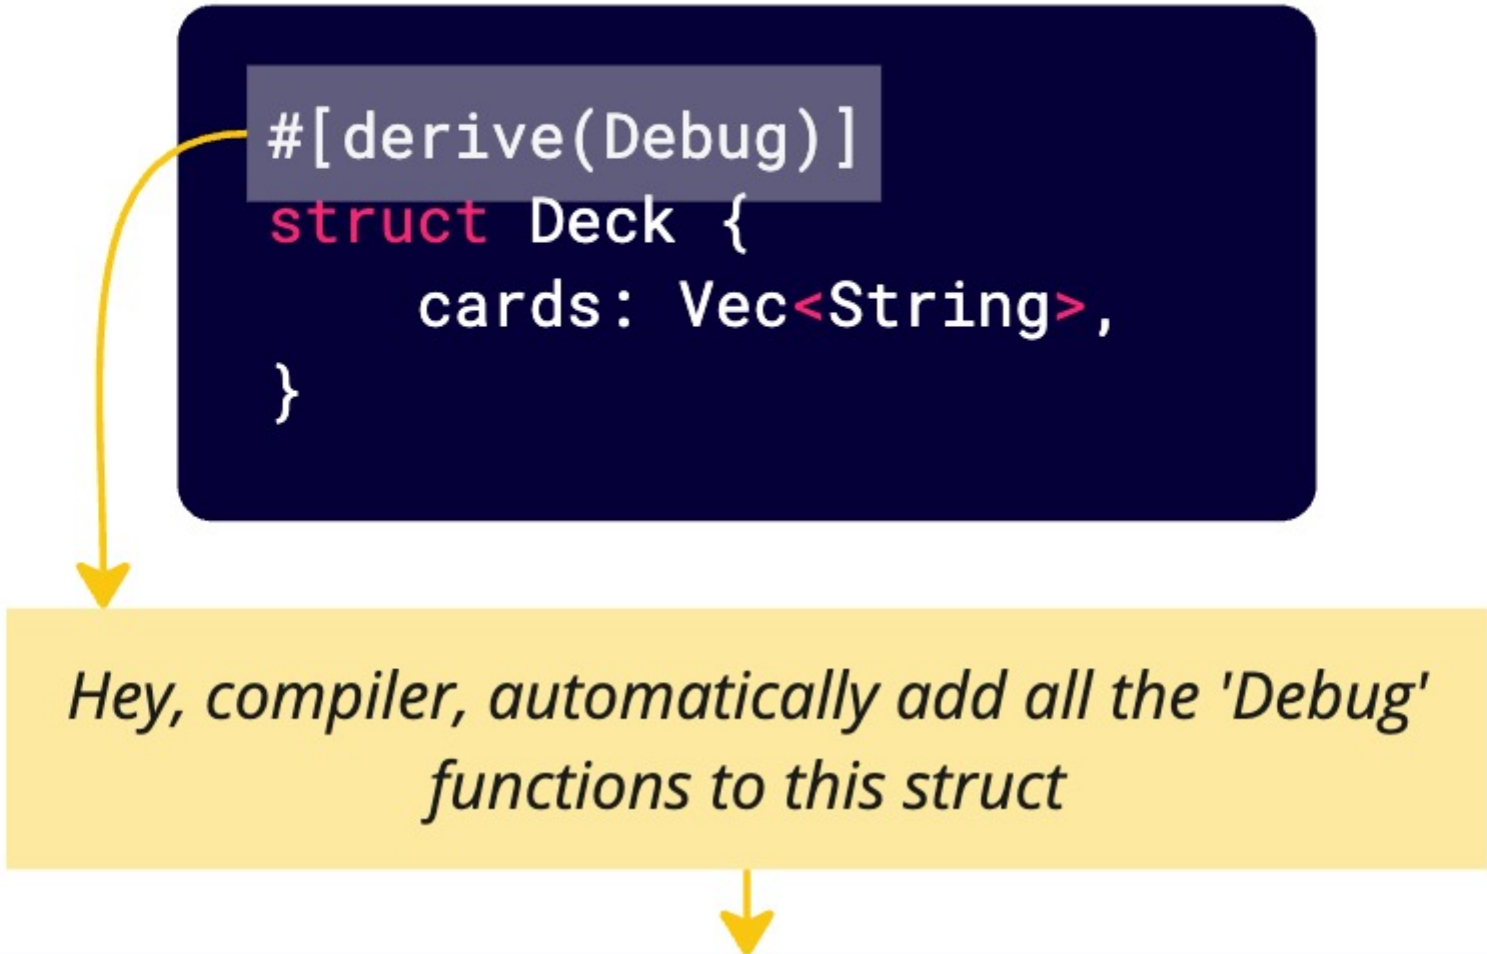

```
#[derive(Debug)]
```

```
struct Deck {  
    cards: Vec<String>,  
}
```

Called the 'Debug' trait

Traits a set of functions

```
#[derive(Debug)]  
struct Deck {  
    cards: Vec<String>,  
}
```

The diagram illustrates the process of deriving the Debug trait for a Rust struct. It starts with a code block containing a struct definition with the `#[derive(Debug)]` attribute. A yellow arrow points from this attribute to a yellow text box that says "Hey, compiler, automatically add all the 'Debug' functions to this struct". Another yellow arrow points from this text box to a larger code block showing the final code after compilation, which includes the struct definition and a function `nicely_print_a_deck` that uses `deck.cards.to_string()`.

*Hey, compiler, automatically add all the 'Debug' functions to this struct*

```
struct Deck {  
    cards: Vec<String>,  
}  
  
// **Imaginary extra functions added to our program  
// by the compiler  
fn nicely_print_a_deck(deck) {  
    // Invalid syntax, added just for clarity  
    return deck.cards.to_string();  
}
```

Bindings are **immutable** (can't change) by default

## Immutable

```
let numbers = vec![];  
  
// Error! Can't change the value  
numbers.push(1); // Error!  
  
// Error! Can't reassign either!  
numbers = vec![];
```

## Mutable

```
let mut numbers = vec![];  
  
// Ok!  
numbers.push(1);  
  
// Ok!  
numbers = vec![];
```

```
let suits = ["Diamonds", "Clubs"];  
let values = ["2", "3", "4", "5"];
```

Creates an **array** of strings.  
Arrays are fixed in size (can't grow/shrink)

```
let suits = vec!["Diamonds", "Clubs"];  
let values = vec!["2", "3", "4", "5"];
```

Creates a **Vector** of strings.  
Vectors are dynamic (they can grow/shrink)

**Are the suits/values lists going to change over time? If not, maybe use an array!**

## Implicit Return

```
fn is_even(num: i32) -> bool {  
    return num % 2 == 0;  
}
```

Same thing!

```
fn is_even(num: i32) -> bool {  
    num % 2 == 0  
}
```

Remember to drop  
the semicolon

```
fn is_even(num: i32) -> bool {  
    if num % 2 == 0 {  
        true  
    } else {  
        false  
    }  
}
```

**Implicit return will  
automatically return the  
last executed expression in  
the function**

Impl definition. Same  
name as struct

```
impl Deck {  
    fn new() {  
        // stuff...  
    }  
  
    fn shuffle(&self) {  
        // stuff...  
    }  
}  
  
fn main() {  
    let deck = Deck::new();  
  
    deck.shuffle();  
}
```

# Inherent Implementations

Fancy term for 'add a function to a struct'

Used to define **methods** and **associated functions**

# Inherent Implementations

Fancy term for 'add a function to a struct'

Used to define **methods** and **associated functions**

```
impl Deck {  
    fn new() {  
        // stuff...  
    }  
  
    fn shuffle(&self) {  
        // stuff...  
    }  
}  
  
fn main() {  
    let deck = Deck::new();  
  
    deck.shuffle();  
}
```

**Associated function**, tied to the struct definition

**Method**, operates on a specific instance of a struct

```
impl Deck {  
    fn new() -> Self {  
        // stuff...  
    }  
}  
  
fn main() {  
    Deck::new();  
}
```

## Associated Functions

Use when you have functionality not tied to a specific instance

**Examples:** 'full\_deck()', 'with\_n\_cards(10)', 'empty\_deck()'

```
impl Deck {  
    fn shuffle(&self) {  
        // stuff...  
    }  
}  
  
fn main() {  
    deck.shuffle();  
}
```

## Methods

Use when you need to read or change fields on a specific instance

**Examples:** shuffling cards, adding a card, removing a card, checking if a card exists

# rand crate

*functions, structs, etc*

## submodule 1

*functions, structs, etc*

## submodule 2

*functions, structs, etc*

Code in all crates + programs is organized into *modules*

Every crate has a 'root' module and might have some additional submodules

Root module

submodule

submodule

# rand crate

*thread\_rng()*

Function that makes a random number generator.  
Located in the root module

**mod seq**

*SliceRandom*

*Trait* that adds a 'shuffle()' method onto all vectors.  
Located in the '**seq**' submodule

**We can create submodules in  
our own project to better  
organize our code**

## rand crate

`thread_rng()`

**mod seq**

`SliceRandom`

I want to use  
something out of this  
external crate

## Our Project

```
mod games;  
  
fn main() {  
    let rng = rand::thread_rng();  
  
    let deck = games::Deck::new();  
}
```

I want to use  
something out of this  
internal module

**mod games**

`struct Deck`

## rand crate

`thread_rng()`

mod seq  
*SliceRandom*

I want to use something out of this external crate

## Our Project

```
mod games;  
  
fn main() {  
    let rng = rand::thread_rng();  
  
    let deck = games::Deck::new();  
}
```

I want to use something out of this internal module

mod games

*struct Deck*

We can directly access **external** crates

To use **internal** modules we use the 'mod' keyword

# rand crate

*thread\_rng()*

*random()*

mod seq

*SliceRandom*

mod rngs

*OsRng*

```
fn main() {  
    let rng = rand::thread_rng();  
    let rand_number = rand::random();  
    let rand_u64 = rand::rngs::OsRng.next_u64();  
}
```

Gets tedious to write out 'rand::xyz'  
repeatedly

# rand crate

*thread\_rng()*

*random()*

mod seq

*SliceRandom*

mod rngs

*OsRng*

```
use rand::{thread_rng, random, rngs::OsRng};
```

```
fn main() {  
    let rng = thread_rng();  
    let rand_number = random();  
    let rand_u64 = OsRng.next_u64();  
}
```

**'use' pulls specific things into the scope  
of this file**

```
impl Deck {  
    fn shuffle(&self) {  
    }  
}
```

Give me a **read only**  
reference to the deck

```
impl Deck {  
    fn shuffle(&mut self) {  
    }  
}
```

Give me a **read/write**  
reference to the deck

# Deck Object

*Represents a collection of playing cards*

*Functionality I want  
this deck to have*

**new()**

Creates a new 'deck' object that contains a list of playing cards

**shuffle()**

Shuffles the order of cards in this deck

**deal(5)**

Removes some playing cards from this deck and returns them in a new Vector

# Crate == Package

## Rust Standard Library

```
graph LR; A[Rust Standard Library] --> B[Included with every project without any additional install]; A --> C[Docs at doc.rust-lang.org/std]; D[External Crates] --> E[Have to be installed into our project with cargo add rand]; D --> F[Crate listing at crates.io]; D --> G[Docs also at docs.rs];
```

Included with every project without any additional install

Docs at

***doc.rust-lang.org/std***

## External Crates

Have to be installed into our project with  
*cargo add rand*

Crate listing at  
***crates.io***

Docs also at  
***docs.rs***

**'Exclusive' range**

`0..4 // 0, 1, 2, 3`

**'Inclusive' range**

`0..=4 // 0, 1, 2, 3, 4`

```
#[derive(Debug, PartialEq)]
enum DeckState {
    Initialized,
    Shuffled,
}

fn main() {
    let deck = Deck::new();

    if deck.state == DeckState::Initialized {
        println!("Deck not yet shuffled");
    } else if deck.state == DeckState::Shuffled {
        println!("Deck has been shuffled!");
    }
}
```

# Enums

A set of values that are related together in some way

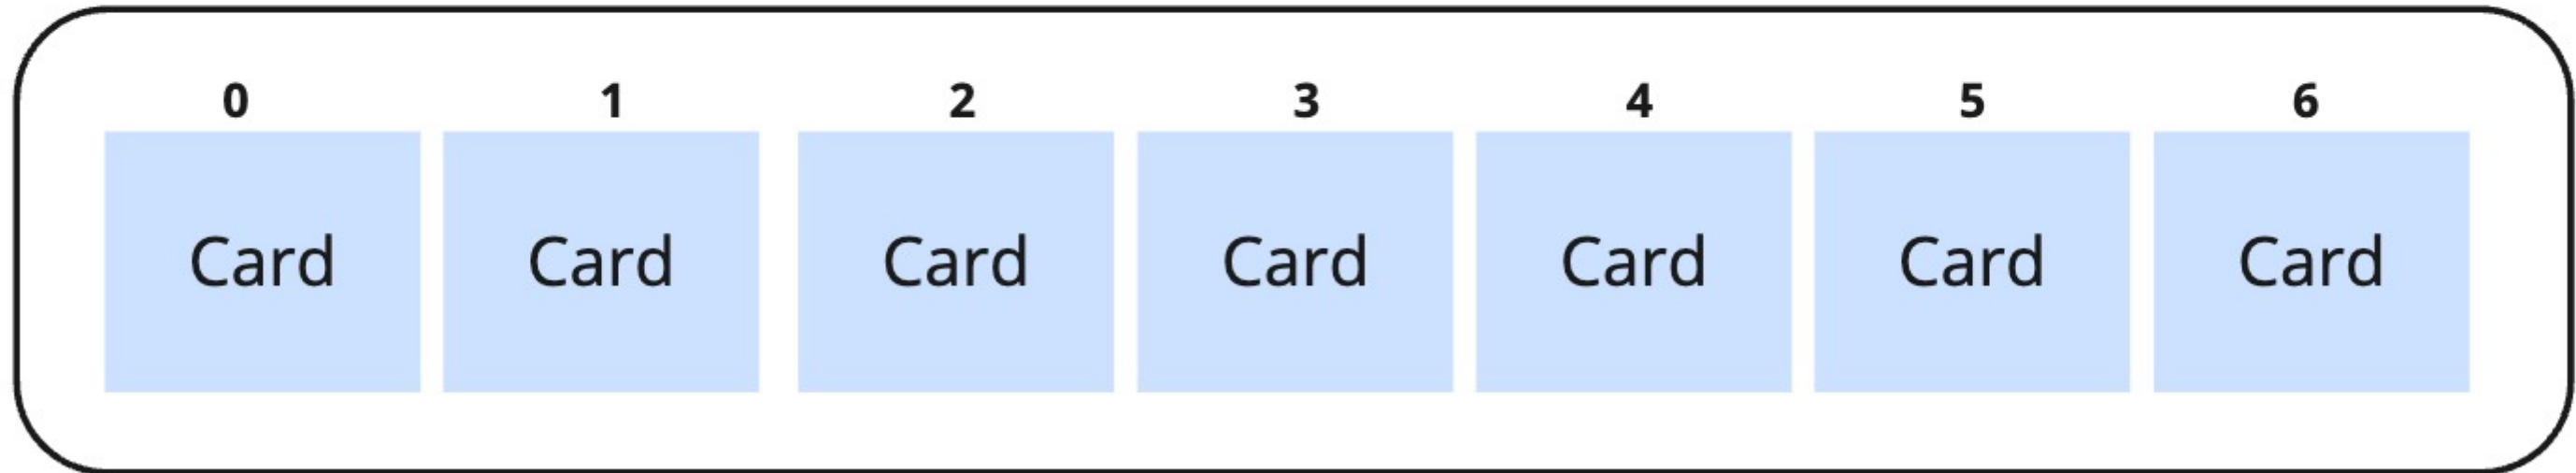

A set of values that are related together in some way

# Types of Numbers

Types	Description	Range
<b>i8</b>	Positive or negative integers	-128 to 127
<b>i16</b>	Positive or negative integers	-32,768 to 32,767
<b>i32</b>	Positive or negative integers	2,147,483,648 to 2,147,483,647
<b>i64</b>	Positive or negative integers	-9.2E18 to 9.2E18
<b>i128</b>	Positive or negative integers	-1.7E38 to 1.7E38
<b>isize</b>	Positive or negative integers	-9.2E18 to 9.2E18
<b>u8</b>	Unsigned integers	0 to 255
<b>u16</b>	Unsigned integers	0 to 65,535
<b>u32</b>	Unsigned integers	0 to 4.29E9
<b>u64</b>	Unsigned integers	0 to 1.84E19
<b>u128</b>	Unsigned integers	0 to 3.4E38
<b>usize</b>	Unsigned integers	0 to 1.84E19
<b>f32</b>	Decimal values	-3.4E38 to 3.4E38
<b>f64</b>	Decimal values	-1.7E308 to 1.7E308

# Vector

```
self.cards.split_off(  
    self.cards.len() - num_cards  
)
```

```
use rand::{seq::SliceRandom, thread_rng};
```

## 'use' Statements

Import code from crates (packages) or other files in your project

You can import multiple things on a single line using curly braces

# Attributes

```
#[derive(Debug)]  
struct Deck {  
    cards: Vec<String>,  
}
```

Provide extra instructions to the compiler

'derive' is an attribute. Tells the compiler to add additional code to the struct

'Debug' is a trait. Has functions included that aid in debugging (like printing a struct)

```
struct Deck {  
    cards: Vec<String>,  
}
```

## Structs

Defines a collection of fields (data) that are related in some way

Can be used to tie together data + functionality if we add an 'impl' block

```
impl Deck {  
    fn new() -> Self {  
        // code  
    }  
  
    fn shuffle(&self) {  
        // code  
    }  
}
```

## Inherent Implementations

Defines methods + associated functions tied to a struct

First argument determines whether we are making a method or an associated function

'**main**' is called automatically when our program starts

'**let mut**' used when we want to make a variable that can be reassigned or when we want to be able to change the value

Error handling is critical, we will spend a lot of time investigating it!

'associated functions' called using the '::' syntax

```
fn main() {  
    let mut deck = Deck::new();  
  
    deck.shuffle();  
    // Probably need to add error handling!!!!  
    let cards = deck.deal(3);  
  
    println!("Heres your hand: {:#?}", cards);  
    println!("Heres your deck: {:#?}", deck);  
}
```

**{:#?}** is a formatter. Prints a struct in a human-readable way
